# 3. Ranking Measures

https://networkx.github.io/documentation/networkx-

1.10/reference/generated/networkx.algorithms.link\_analysis.pagerank\_alg.pagerank.html

PageRank computes a ranking of the nodes in the graph G based on the structure of the incoming links.

Mathematical PageRanks for a simple network, expressed as percentages. (Google uses a logarithmic scale.) Page C has a higher PageRank than Page E, even though there are fewer links to C; the one link to C comes from an important page and hence is of high value. If web surfers who start on a random page have an 85% likelihood of choosing a random link from the page they are currently visiting, and a 15% likelihood of jumping to a page chosen at random from the entire web, they will reach Page E 8.1% of the time. (The 15% likelihood of jumping to an arbitrary page corresponds to a damping factor of 85%) Without damping, all web surfers would eventually end up on Pages A, B, or C, and all other pages would have PageRank zero. In the presence of damping, Page A effectively links to all pages in the web, even though it has no outgoing links of its own.

### 3.1 Page Ranking

https://en.wikipedia.org/wiki/PageRank

```
In [0]:
if not os.path.isfile('data/fea sample/page rank.p'):
    pr = nx.pagerank(train_graph, alpha=0.85)
    pickle.dump(pr,open('data/fea_sample/page_rank.p','wb'))

# 5.4 Adding new set of features

we will create these each of these features for both train and test data points

- 1. Weight Features
  - · weight of incoming edges
  - · weight of outgoing edges
  - weight of incoming edges + weight of outgoing edges
  - weight of incoming edges \* weight of outgoing edges
  - 2\*weight of incoming edges + weight of outgoing edges
  - weight of incoming edges + 2\*weight of outgoing edges
- 2. Page Ranking of source
- 3. Page Ranking of dest
- 4. katz of source
- 5. katz of dest
- 6. hubs of source
- 7. hubs of dest
- 8. authorities s of source
- 9. authorities\_s of dest

#### Weight Features

In order to determine the similarity of nodes, an edge weight value was calculated between nodes. Edge weight decreases as the neighbor count goes up. Intuitively, consider one million people following a celebrity on a social network then chances are most of them never met each other or the celebrity. On the other hand, if a user has 30 contacts in his/her social network, the chances are higher that many of them know each other. credit - Graph-based Features for Supervised Link Prediction William Cukierski, Benjamin Hamner, Bo Yang

\begin{equation} W = \frac{1}{\sqrt{1+|X|}} \end{equation}

it is directed graph so calculated Weighted in and Weighted out differently

#### In [0]:

```
#weight for source and destination of each link
Weight in = {}
Weight out = {}
for i in tqdm(train graph.nodes()):
    s1=set(train graph.predecessors(i))
    w in = 1.0/(np.sqrt(1+len(s1)))
    Weight_in[i]=w_in
    s2=set(train graph.successors(i))
    w \text{ out} = 1.0/(\text{np.sqrt}(1+\text{len}(s2)))
    Weight out[i]=w out
#for imputing with mean
mean weight in = np.mean(list(Weight in.values()))
mean weight out = np.mean(list(Weight out.values()))
100%|
                                                                              | 1780722/1780722 [00:11<00:00
